By means of resonant inelastic x-ray scattering at the Cu  $L_3$  edge, we measured the spin-wave dispersion along  $\langle 100 \rangle$  and  $\langle 110 \rangle$  in the undoped cuprate Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>. The data yield a reliable estimate of the superexchange parameter  $J=135\pm 4$  meV using a classical spin-1/2 two-dimensional Heisenberg model with nearest-neighbor interactions and including quantum fluctuations. Including further exchange interactions increases the estimate to J=141 meV. The 40 meV dispersion between the magnetic Brillouin zone boundary points (1/2, 0) and (1/4, 1/4) indicates that next-nearest-neighbor interactions in this compound are intermediate between the values found in La<sub>2</sub>CuO<sub>4</sub> and Sr<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>. Due to the low-Z elements composing Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>, the present results may enable a reliable comparison with the predictions of quantum many-body calculations, which would improve our understanding of the role of magnetic excitations and of electronic correlations in cuprates.

# DOI: 10.1103/PhysRevB.95.155110

#### I. INTRODUCTION

Magnetic excitations have been intensively studied in high-temperature superconducting (HTS) cuprates for their possible role in the pairing mechanism of these materials [1–4]. Although several studies have already been carried out by means of inelastic neutron scattering (INS) [3] on a number of cuprate compounds, the interpretation of the data remains highly controversial because of the lack of a theoretical understanding of electronic correlations in realistic systems.

Recently, Cu  $L_3$  edge resonant inelastic x-ray scattering (RIXS) [5,6] has emerged as an alternative probe of the above excitations. This technique extends the energy range probed by INS to higher energies [7], and it also offers the advantage of measuring small single crystals. To the best of our knowledge, in HTS cuprates, RIXS has been hitherto employed to complete previous INS studies on well-known compounds. In the case of  $La_{2-x}Sr_xCuO_4$ , for example, the RIXS results found that magnetic excitations persist up to very high doping levels in regions of the Brillouin zone that are not easily probed by INS [8].

The purpose of the present work is to study by means of RIXS the HTS cuprate parent compound  $Ca_2CuO_2Cl_2$  (CCOC), for which INS studies are infeasible because samples are only available as small, hygroscopic single crystals. This parent compound can be doped either with sodium,  $Ca_{2-x}Na_xCuO_2Cl_2$  (Na-CCOC) [9,10], or with vacancies,  $Ca_{2-x}CuO_2Cl_2$  [11]. The motivation of our study is the simplicity of their single-layer tetragonal structure and the absence of structural instabilities that often jeopardize the study of more common cuprates, such as the aforementioned  $La_{2-x}Sr_xCuO_4$ . Moreover, the  $Ca_2CuO_2Cl_2$  system is

the only HTS cuprate system composed exclusively of low Z ions, with copper being the heaviest. This is an advantage for standard ab initio density-functional-theory calculations, where large Z ions pose problems for pseudopotential optimization. This feature is even more advantageous for advanced theoretical methods suitable to take into account correlation effects, such as quantum Monte Carlo, since they require one to treat accurately the spin-orbit coupling. To circumvent this difficulty, these quantum many-body calculations are mainly applied to systems with light atoms, where relativistic effects are negligible [12–14]. Note that Ref. [14] treats in particular Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>, although without separating the different components of the magnetic exchange interaction. In this respect,  $Ca_{2-x}CuO_2Cl_2$  and  $Ca_{2-x}Na_xCuO_2Cl_2$  are the most suitable example of such low-Z systems among HTS cuprates. In addition, the superconducting compound Ca<sub>2-x</sub>Na<sub>x</sub>CuO<sub>2</sub>Cl<sub>2</sub> has already been studied by means of photoemission and scanning tunneling spectroscopy [9,15,16], therefore a RIXS study is expected to provide further insight into the electronic excitation spectrum. In the present work, by means of RIXS, we study the spin-wave dispersion of Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>, the parent compound of the above HTS cuprate, and we extract the superexchange parameter J using two different models.

#### II. EXPERIMENTAL METHODS

### A. Crystal growth and characterization

Single crystals of Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> were grown from CaCO<sub>3</sub>, CuO, and CaCl<sub>2</sub> by solid state reaction, as described in detail elsewhere [10,11]. As shown in Fig. 1, Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> has a tetragonal K<sub>2</sub>NiF<sub>4</sub>-type structure (I4/mmm) [19] with alternate stacking of (Ca,Cl)<sub>2</sub> and CuO<sub>2</sub> layers. The lattice parameters at ambient conditions are a = b = 3.867 35(2) Å

<sup>\*</sup>matteo.dastuto@impmc.upmc.fr

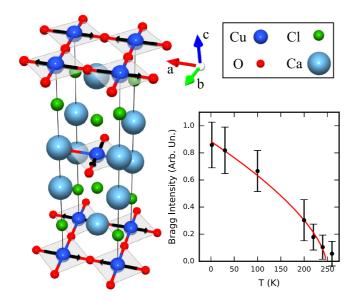

FIG. 1. Top left: Tetragonal crystal structure [17] of  $Ca_2CuO_2Cl_2$  [11]. The square coordination of copper with its four nearest-neighbor oxygen ions in the  $CuO_2$  planes is shown. The chlorine ions are located in the apical site above and below the copper. Black arrows indicate one of the possible magnetic structures consistent with neutron-diffraction data [18]. Bottom right: Temperature dependence of the fitted intensity of the averaged Bragg reflections  $(\frac{1}{2},\frac{1}{2},\frac{5}{2})$  and  $(\frac{1}{2},\frac{1}{2},\frac{7}{2})$  and a power-law fit (red).

and c = 15.0412(1) Å [10,11]. The crystals are easily cleaved along the ab plane due to the weak ionic bonds between adjacent layers.

The single crystals of  $\approx 2$  mm width/height and  $\approx 0.2$  mm thickness were characterized using a commercial Bruker four-circle  $\kappa$  geometry diffractometer. A fixed Mo anode was used and the filtered  $K\alpha$  emission was collimated at 0.2 mm (3 mrad). A cryogenic  $N_2$  flux was used to isolate the sample from humidity. The measurements yield unit-cell parameters in agreement with the literature [10,11], and they also enabled us to determine the crystal orientation with respect to visible facets. The samples for RIXS measurements were subsequently glued on the holder with silver epoxy. Finally, ceramic posts were attached with the same epoxy in order to cleave the crystals in vacuum.

Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> is an antiferromagnetic insulator with a Néel temperature of  $T_N=247\pm 5$  K [18]. To check the magnetic state of the samples, we performed neutron scattering on the 1T spectrometer at Laboratoire Leon–Brillouin using a sample from the same batch used for the RIXS experiment. We measured very weak magnetic reflections at low temperature for  $\mathbf{q}=(\frac{1}{2},\frac{1}{2},\frac{\ell}{2})$  with  $\ell=2n+1$  ( $n=0,\ldots,4$ ), but none for  $\ell=0$ , in agreement with Ref. [18]. The temperature dependence of the fitted Bragg intensity [average of the  $(\frac{1}{2},\frac{1}{2},\frac{5}{2})$  and  $(\frac{1}{2},\frac{1}{2},\frac{7}{2})$  reflections] is shown in the bottom right of Fig. 1, and a power-law fit finds  $T_N=247\pm 6$  K.

### B. Resonant inelastic x-ray scattering

RIXS measurements at the Cu  $L_3$  edge (930 eV) were performed at the ADRESS beamline [21,22] of the Swiss Light

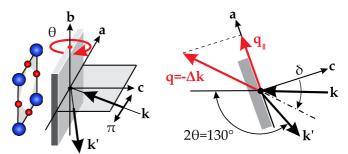

FIG. 2. RIXS geometry for measuring along  $\langle 100 \rangle$  with  $\pi$ -polarization and grazing out emission (modified from Ref. [20]). The scattering angle  $2\theta$  is defined between the photon momentum of the incoming beam  ${\bf k}$  and the direction where the analyzer collects the scattered beam  ${\bf k}'$ .  $2\theta$  and the azimuthal angles are fixed, whereas the incident angle can be changed by a rotation,  $\theta$ , around the b axis. The incident angle defines  $\delta$ , which is the angle between the sample normal  ${\bf c}$  and the transferred momentum  ${\bf q}$  (red arrow), so that  $\delta=0$  in specular reflection. The projection of  ${\bf q}$  onto the sample's ab plane is denoted  ${\bf q}_{\parallel}$ , which is 0 for  $\delta=0$  and maximal for grazing geometries. Measurements along  $\langle 110 \rangle$  are done with the sample rotated  $45^{\circ}$  around the c axis.

Source using the SAXES spectrometer [23]. The samples were mounted in the ultrahigh-vacuum manipulator cryostat of the experimental station. By applying a force on the aforementioned ceramic posts, the samples were cleaved *in situ* under ultrahigh vacuum and low-temperature conditions to avoid hygroscopic damage of the cleaved surface. Their surface quality was confirmed by x-ray absorption spectroscopy. All spectra presented in this work were taken at 15 K.

The experimental geometry is shown in Fig. 2 and was similar to previous RIXS studies on cuprate parent compounds [6]. We used  $\pi$ -polarized incident x rays and a grazing exit geometry in order to enhance the single magnon spectral weight [7,24–29]. The scattering angle was fixed at  $2\theta = 130^{\circ}$ , giving a constant momentum transfer to the sample of q = $2k \sin(\theta) = 0.85 \text{ Å}^{-1}$ . Although q is fixed, its component in the ab plane,  $q_{\parallel}$ , can be changed by rotating the sample about the vertical axis (b axis in Fig. 2). For a given rotation,  $\theta$ , the deviation from specular reflection is given as  $\delta = \theta_{\text{specular}} - \theta$ , thus  $q_{\parallel} = q \sin(\delta)$ . The minimum (maximum)  $\delta$  used was  $+5^{\circ}$  $(+55^{\circ})$  corresponding to  $q_{\parallel} = +0.07 \text{ Å}^{-1} (q_{\parallel} = +0.70 \text{ Å}^{-1}).$ Therefore, in terms of reciprocal-lattice units  $(2\pi/a)$  in the abplane, we measured  $\mathbf{q}_{\parallel}$  from (0.05, 0) to (0.43, 0) along  $\langle 100 \rangle$ and from (0.03, 0.03) to (0.3, 0.3) along  $\langle 110 \rangle$ . In other terms (Fig. 6, inset), we measured past the magnetic Brillouin zone along  $\Gamma$ -M, but well short of where thermal neutrons measure at M = (1/2, 1/2). Along  $\Gamma$ -X we measured very close to the first Brillouin zone edge at X = (1/2,0).

#### III. RESULTS AND DISCUSSION

The RIXS map of  $Ca_2CuO_2Cl_2$  at  $\mathbf{q}_{\parallel} = (0.34,0)$  shown in Fig. 3 highlights the resonant behavior of the inelastic features. From lower- to higher-energy loss, one notes a midinfrared peak between 0.1 and 0.6 eV, dd excitations between 1 and 3 eV, and weak charge-transfer excitations at higher energies. A weak fluorescence line is visible at energies above the

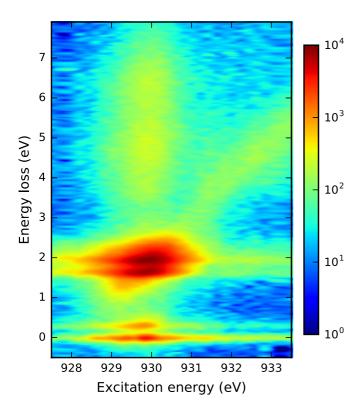

FIG. 3. RIXS map at  $\mathbf{q}_{\parallel}=(0.34,0)$  with  $\pi$  incidence polarization showing the resonant behavior of the magnetic excitations, dd excitations, and charge-transfer excitations. Weak fluorescence is seen at high energy when the system is excited above the Cu  $L_3$  edge threshold. The color map is a logarithmic scale in arbitrary intensity units.

Cu  $L_3$  edge and intersects the dd excitations at resonance. The spectral weight from this fluorescence line at resonance is unknown, but it is likely of the same order as the dd excitations, as evidenced by the diagonal skew of the dd excitations.

Figure 4 shows the RIXS spectra obtained along both directions focusing on the midinfrared energy region, while Fig. 5(a) shows the full energy region for  $\delta = +10$  and +55. The spectra are normalized to the area of the dd excitations to account for the geometrical changes of the RIXS cross section. There is an expected increase in elastic scattering near specular, i.e., at (0.09, 0) and (0.06, 0.06). However, the elastic line for the sample aligned along  $\langle 100 \rangle$  was large for all momentum transfers. These variations are likely due to finite surface quality after cleaving and did not impede accurate fitting.

The midinfrared feature is assigned as a magnon with a higher-energy multimagnon continuum. This assignment was done considering its dispersion (Figs. 4 and 6) and past RIXS results on cuprate parent compounds in this experiment geometry [6,7]. Furthermore, in our case, magnetic excitations are the only excitation in the midinfrared energy region due to the  $\approx$ 2 eV Mott gap. These spin excitations are the focus of our paper and are discussed below.

The apical chlorine in  $Ca_2CuO_2Cl_2$  increases the tetragonal distortion much like for  $Sr_2CuO_2Cl_2$ , therefore based on Ref. [20] we assigned the dd excitation at 1.70 eV to Cu  $3d_{xy}$ , 1.99 eV to Cu  $3d_{xz/yz}$ , and higher energies in the shoulder to Cu  $3d_{3z^2-r^2}$ . The dd excitations were not well fit following the

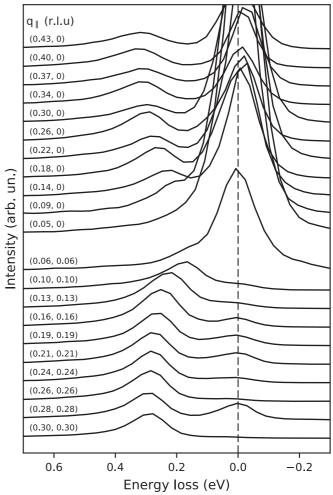

FIG. 4. RIXS spectra showing the dispersion of the magnetic excitations along  $\langle 100 \rangle$  (top) and  $\langle 110 \rangle$  (bottom). Spectra are normalized by their dd excitations.

technique of Ref. [20], possibly due to fluorescence emission in this energy region or electron-phonon coupling [30].

The broad charge-transfer feature centered around 5.5 eV did not show dispersion or significant intensity variations, in agreement with Cu K edge RIXS [31]. The author of Ref. [31] assigned this feature as transitions to an excited state composed of symmetric contributions of a central Cu  $3d_{x^2-y^2}$  orbital and the surrounding O  $2p_\sigma$  orbitals. Cu K edge RIXS also found a dispersive Mott excitation from 2.35 to 3.06 eV along  $\Gamma$ -X and from 2.34 to 4.14 eV along  $\Gamma$ -X. Therefore, the Mott excitation will fall under the dd excitations for the majority of our momentum transfers, however the Mott excitation at  $\approx$ 3.4 eV for  $\mathbf{q}_{\parallel} = (0.3,0.3)$  is not visible in our results [Fig. 5(a)].

A typical fit of the midinfrared region is shown for  $q_{\parallel}=(0.21,0.21)$  in Fig. 5(b) and the extracted magnon dispersion is shown in Fig. 6. The resolution function was measured on carbon tape and was well described by a Lorentzian squared function of 130 meV full width at half-maximum. The elastic, phonon, and single magnon contributions were all resolution-limited. The multimagnon excitation continuum was modeled as the resolution function convolved with a step function with subsequent exponential decay toward higher-energy losses.

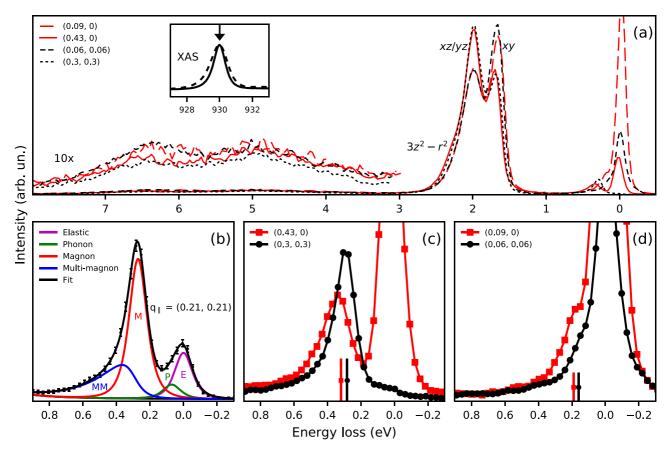

FIG. 5. Cu  $L_3$  RIXS spectra of Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> at different in-plane transferred momentum,  $\mathbf{q}_{\parallel}$ , expressed as (h, k) in reciprocal-lattice units. (a) Representative RIXS spectra along  $\langle 100 \rangle$  (red) and  $\langle 110 \rangle$  (black). All spectra have been normalized to the area of the dd excitations. The midinfrared regions of these spectra are shown in (c,d), where vertical bars represent the energy of a single magnon found by fitting. The inset shows TEY-XAS (solid) and TFY-XAS (dashed), with an arrow indicating incident energy for our RIXS measurements. (b) Example of the fitting procedure at  $\mathbf{q}_{\parallel} = (0.21, 0.21)$  shown as a black curve through data points. The elastic (E, magenta), phonon (P, green), and single magnon (M, red) peaks were resolution-limited, and the multimagnon (MM, blue) peak fitting is described in the text.

The background was a Lorentzian tail of the form  $y = A(x - x_0)^{-2} + c$ . The energy of the phonon contribution is found around 60–70 meV with respect to the elastic, or ~15–17 THz, roughly corresponding to the Debye cutoff frequency  $\omega_D$  of Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> [32]. The major source of uncertainty for the magnon energy was determining the elastic energy, since the elastic line was irregular for the sample aligned along  $\langle 100 \rangle$  and often too weak along  $\langle 110 \rangle$ . dd excitations in undoped layered cuprates are known to be nondispersive within current experimental accuracy [20], therefore the elastic energy was fixed with respect to the Cu  $3d_{xz/yz}$  energy, which was found to be 1985  $\pm$  5 meV from several spectra with well-defined elastic lines.

The experimental and calculated dispersion along the two high-symmetry directions is shown together in Fig. 6. We use a classical S = 1/2 2D Heisenberg model with higher-order coupling to analyze our dispersion. The Hamiltonian is given by [33]

$$\mathcal{H} = J \sum_{\langle i,j \rangle} \mathbf{S}_{i} \cdot \mathbf{S}_{j} + J' \sum_{\langle i,i' \rangle} \mathbf{S}_{i} \cdot \mathbf{S}_{i'} + J'' \sum_{\langle i,i'' \rangle} \mathbf{S}_{i} \cdot \mathbf{S}_{i''}$$

$$+ J_{c} \sum_{\langle i,j,k,l \rangle} \{ (\mathbf{S}_{i} \cdot \mathbf{S}_{j})(\mathbf{S}_{k} \cdot \mathbf{S}_{l}) + (\mathbf{S}_{i} \cdot \mathbf{S}_{l})(\mathbf{S}_{k} \cdot \mathbf{S}_{j})$$

$$- (\mathbf{S}_{i} \cdot \mathbf{S}_{k})(\mathbf{S}_{j} \cdot \mathbf{S}_{l}) \},$$

where we include first-, second-, and third-nearest-neighbor exchange terms, as well as a ring exchange term  $(J, J', J'', \text{ and } J_c)$ . Within classic linear spin-wave theory [34,35], this leads to a dispersion relation given by [33]  $\hbar\omega_{\mathbf{q}} = 2Z_C(\mathbf{q})\sqrt{A_{\mathbf{q}}^2 - B_{\mathbf{q}}^2}$ , where  $A_{\mathbf{q}}^2 = J - J_c/2 - (J' - J_c/4)(1 - \nu_h \nu_k) - J''[1 - (\nu_{2h} + \nu_{2k})/2]$ ,  $B_{\mathbf{q}}^2 = (J - J_c/2)(\nu_h + \nu_k)/2$ ,  $\nu_x = \cos(2\pi x)$ , and  $Z_C(\mathbf{q})$  is a spin renormalization factor [33,36].

As a first approximation, we consider only the first term in the Hamiltonian, which corresponds to only nearest-neighbor exchange. In this isotropic case, the dispersion relation above reduces to  $\hbar\omega_{\bf q}=2JZ_C\sqrt{1-[\cos(2\pi h)+\cos(2\pi k)]^2/4}$ , where  $Z_c=1.18$  is a constant [36]. The calculation for our data is shown in Fig. 6 as a solid red line, obtained both analytically and using the SPINWAVE code [35], as a check. The energy at the zone boundary peaks at  $2JZ_C=320\pm10$  meV, which gives  $J=135\pm4$  meV. For La<sub>2</sub>CuO<sub>4</sub> and Sr<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>, the zone boundary energy is  $314\pm7$  and 310 meV, respectively, which corresponds to  $J=133\pm3$  and 131 meV, respectively [7,33].

Note the  $40 \pm 10$  meV energy difference along the magnetic Brillouin zone boundary (MBZB) between X and M. This MBZB dispersion is an indication of non-negligible magnetic

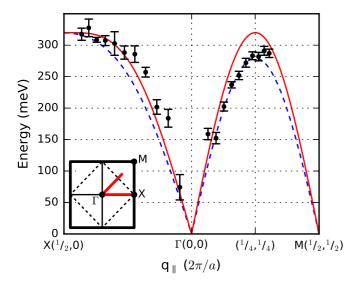

FIG. 6. Dispersion of  $\text{Ca}_2\text{CuO}_2\text{Cl}_2$  measured using  $\text{Cu }L_3$  RIXS. The red, continuous line is a calculation for a classical spin-1/2 2D Heisenberg model with nearest-neighbor exchange, and the blue, dashed line is a calculation including further exchange terms that is described in the text. Inset: 2D Brillouin zone showing high-symmetry points. The first Brillouin zone boundary is represented by a thick black square, while the magnetic Brillouin zone boundary is represented by a dashed line. The region where we measured is shown as two thick red lines along  $\Gamma$ -X and  $\Gamma$ -M.

interactions beyond nearest neighbors [7,33,37]. Following Ref. [33], we parametrize the above Hamiltonian with a single-band Hubbard model with U, the on-site repulsion, and t, the nearest-neighbor hopping. Expanding the Hubbard Hamiltonian to order  $t^4$ , we find  $J = 4t^2/U - 24t^4/U^3$ ,  $J_c = 80t^4/U^3$ , and  $J' = J'' = 4t^4/U^3$ . We assume the spin renormalization is constant,  $Z_c(\mathbf{q}) \approx Z_c$ , which introduces an error less than the uncertainty of our data [33]. Within this model, it can be shown [38] that the maximum energy at X is given by  $E_{\text{max}} = 2Z_C(J - J_c/10)$  and the energy dispersion along the MBZB is given as  $\Delta E_{\text{MBZB}} = 3Z_C J_c/5$ . We can use our experimental dispersion to fix  $E_{\text{max}} = 320 \text{ meV}$ and  $\Delta E_{\text{MBZB}} = 40$  meV, which uniquely determines U =2.2 eV and t = 295 meV. The corresponding superexchange parameter is J = 141 meV, versus J = 146 meV for La<sub>2</sub>CuO<sub>4</sub> and J = 144 meV for  $Sr_2CuO_2Cl_2$ . The calculated dispersion using these values is shown in Fig. 6 as a dashed blue line. The MBZB dispersion is well fit, however the energy along (100) is underestimated, indicating the need to include further hopping terms in the Hubbard model [37,39]. Furthermore, our values of U and t are unphysical, even if they are similar to those found in La<sub>2</sub>CuO<sub>4</sub> at 10 K using this approach [33] (U = 2.2 eV and t = 300 meV). They are in disagreement with photoemission results [40], and U = 7.5t is less than the tight-binding bandwidth [39] of 8t. Inclusion of further hopping terms is beyond the scope of this paper, however they will not fundamentally change the determination of the superexchange parameter J.

The fact that all three cuprates discussed above have a very similar  $E_{\rm max}$  is a bit surprising. The simplistic scaling relation [41]  $J \propto d_{\rm NN}^{-4}$  based on the intraplanar Cu NN distance

would predict a 7% softening of  $Ca_2CuO_2Cl_2$  with respect to  $La_2CuO_4$  ( $d_{NN} = 3.803$  Å) [42] and an 11% hardening with respect to  $Sr_2CuO_2Cl_2$  ( $d_{NN} = 3.975$  Å) [42].

On the other hand, these three cuprates have different  $\Delta E_{\rm MBZB}$ , with La<sub>2</sub>CuO<sub>4</sub> being smaller (22 ± 10 meV) and Sr<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> being larger (70 meV). With further exchange terms [43] it is found that the dispersion scales as  $(t'/t)^2$ , where t' is the next-nearest-neighbor hopping. This second hopping term is typically decreased due to apical hybridization [44], therefore we would expect greater dispersion for longer apical bonds lengths. This is indeed the trend we see for these three compounds: Sr<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> (2.8612 Å) > Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> (2.734 Å) > La<sub>2</sub>CuO<sub>4</sub> (2.416 Å). If this interpretation is correct, then our assignment of the shoulder in the dd excitations to Cu  $3d_{3z^2-r^2}$  is likely incorrect since we would then expect  $E_{3z^2-r^2}$  for Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> to be less than 1.97 eV (Sr<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>) and more than 1.7 eV (La<sub>2</sub>CuO<sub>4</sub>) [20].

Although Ref. [14] did not report a value of J, the current uncertainty in QMC calculations allows a rough comparison between them and experiment. QMC calculations [12,13] have found J = 160(13) meV for La<sub>2</sub>CuO<sub>4</sub>, J = 140(20) meV for CaCuO<sub>2</sub>, and J = 159(14) meV for Ca<sub>2</sub>CuO<sub>3</sub>. The value found for La<sub>2</sub>CuO<sub>4</sub> is quite different from its experimental value, possibly due to relativistic effects in the La atoms. CaCuO<sub>2</sub> and Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> are both composed of CuO<sub>2</sub> planes with interplanar Ca atoms, however CaCuO<sub>2</sub> lacks any apical ligand. Nonetheless, its calculated value matches quite well our results above, much better than the Cu chain system of Ca<sub>2</sub>CuO<sub>3</sub>, which has apical oxygens, emphasizing the important role that the apical ligands play in intraplanar (chain) exchange.

# IV. CONCLUSIONS

In conclusion, the present Cu  $L_3$  edge RIXS study enabled us to determine the spin-wave dispersion along the two high-symmetry directions of Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>, an undoped antiferromagnetic HTS cuprate parent compound containing only low-Z elements. In a first approximation, the data are explained within a simple S = 1/2 2D Heisenberg model with a nearest-neighbor exchange term  $J = 135 \pm 4$  meV, taking into account spin quantum fluctuation renormalization. Including next-nearest-neighbor contributions, our estimate is increased to J = 141 meV. To the best of our knowledge, this is the first measurement of the spin-wave dispersion and of its zone-boundary energy in Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub>, noting that INS experiments are currently infeasible, and two-magnon Raman scattering has not been performed yet. We believe that the present low-Z cuprate Ca<sub>2</sub>CuO<sub>2</sub>Cl<sub>2</sub> is an ideal playground for future quantum many-body theoretical models of HTS cuprates. Our RIXS results combined with the future results of these models will offer a unique comparison between experiment and state-of-the-art theory of correlated electron systems.
